

LESSON HANDOUT

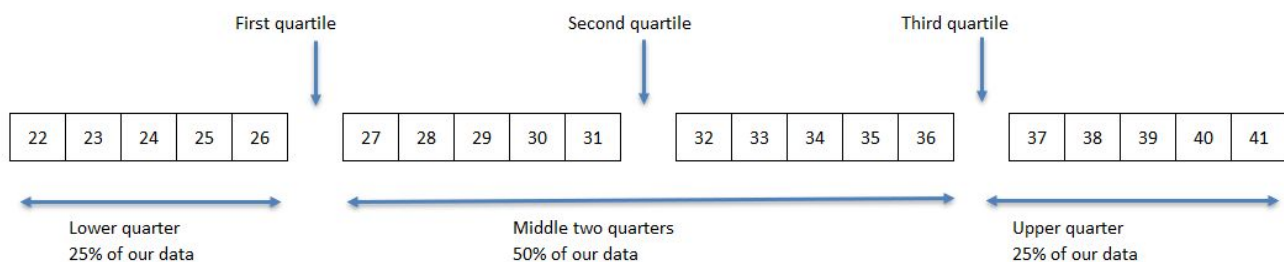

Quartiles and percentiles

Quartiles & percentiles are both ways we can divide our data to help us measure how our data is spread. Additionally, they can assist in calculating a single value's significance.

Quartiles

Quartiles divide our data into four quarters such that:

- Values below the first quartile is the lower quarter, where 25% of our data resides
- Values between the first and third quartile are the middle two quarters, where 50% of our data resides
- Values above the third quartile is the upper quarter where 25% of our data resides

Interquartile range

The interquartile range (IQR) is the range of our middle two quarters and is calculated by subtracting the first quartile by the third quartile. The interquartile range is a measure of how spread apart our values are from the median and can be used to detect outliers. Generally, any value which lies more than 1.5 times the IQR above the third quartile or below the first quartile is considered a moderate outlier and those which lie more than 3 times the IQR are considered strong outliers.

Calculating Quartiles and the IQR

Calculating Quartiles is quite simple with the use of the Excel formula **=QUARTILE**

- **=QUARTILE**(array, quartile to return)

=QUARTILE(flavors_of_cacao!H:H,

QUARTILE(array, quart)	E	F
0 - Minimum value		
1 - First quartile (25th percentile)		
2 - Median value (50th percentile)		
3 - Third quartile (75th percentile)		
4 - Maximum value		

Specific Bean Origin	Rev
Grande	1876
e	1676
ne	1676

2015 70% France

To calculate the **IQR**, subtract the first quartile from the third quartile.

- $= (Q3 - Q1)$, as seen in the screenshot below:

Ratings	Quartiles
Q1	1.20
Q2	2.80
Q3	4.95
IQR	$=C6-C4$

The upper outlier can be calculated by Q3 plus 1.5 times the IQR:

- $= Q3 + (IQR * 1.5)$

Ratings	Quartiles
Q1	1.20
Q2	2.80
Q3	4.95
IQR	3.75
Upper Outlier	$=C6+(C7*1.5)$
Lower Outlier	

And the lower outlier can be calculated by Q1 minus 1.5 times the IQR

- $= Q1 - (IQR * 1.5)$

Ratings	Quartiles
Q1	1.20
Q2	2.80
Q3	4.95
IQR	3.75
Upper Outlier	10.58
Lower Outlier	$=C4-(C7*1.5)$

NOTE: You won't always have logical outliers - in the example screenshots above, if the 'Ratings' were from 0 - 10, you wouldn't have any upper or lower outliers as the number falls outside of the minimum and maximum ranges.

Percentiles

Quartiles are just one way to split our data apart. We could instead choose to split our data into five segments (quantiles) for ten segments (deciles), but this is much less common. We can split our data into different segments by using percentiles.

- A percentile is the value below which a percentage of your data falls. For example, the 33rd percentile is above 33% of values in the dataset.

- We can also find out where a value sits in comparison to the dataset with its percentile rank - the % of values this value is above. For example, a person who is in the 50th percentile rank height is taller than half of those included in the dataset.

Classifying your dataset:

You can classify your dataset by using Quartiles and VLOOKUP.

First, build your table so you have classes from Very Low through to Very high (you can use more appropriate wording for the data you are using) and use your Quarterlies and outliers to fill in the classes. For example:

Fig 1:

Lower Outlier	Very Low
Q1	Low
Q2	Medium
Q3	High
Upper Outlier	Very High

Fig 2:

57	very low
72	low
77	medium
82	high
97	very high

Then, use VLOOKUP and an APPROXIMATE MATCH to calculate the class. What the approximate match does is take the number and find the closest value *lower* than itself.

- =VLOOKUP(cell to calculate, range of your classification table, column index number, TRUE)

IM

X ✓ fx =VLOOKUP(B2,\$F\$2:\$G\$6,2,TRUE)

A	B	C	D	E	F	G
Full Name	Weight (kg)	class				
Bernd Leno	83	TRUE)			57	very low
Héctor Beller	74	low			72	low
Kevin De Bruy	70	very low			77	medium
Virgil van Dijk	92	high			82	high
Sokratis	85	high			97	very high
Maout Özil	76	low				

When classifying in this way, it's a good idea to provide your classification within the data dictionary.

Calculating Percentiles:

You can quickly calculate percentiles by using the formula **=PERCENT RANK**. It returns the rank of a value in a dataset as a percentage of the dataset.

- **=PERCENTRANK**(array, x) - Where "x" is the value
- Remember to change the format to Percentage using the % button

Screenshot example below:

JM						
=PERCENTRANK(B:B,[@[Weight (kg)]])						
A	B	C	D	E	F	
Full Name	Weight (kg)	class	% rank			
Bernd Leno	83	high	t (kg)]])		57	ver
Héctor Beller	74	low	33%		72	lov
Kevin De Bruy	70	very low	15%		77	me
Virgil van Dijk	92	high	96%		82	hig
Sokratis	85	high	81%		97	ver
Mesut Özil	76	low	42%
